Benchmark of error rate inference from UMI-tagged data and PCR error model

Mikhail Shugay November 6, 2016

Load data from 2 independent experiments with 10 different PCR assays. Data was ran with different quality and UMI size threshold:

```
library(plyr)
library(ggplot2)
library(RColorBrewer)
df <- data.frame()</pre>
for (q in c(20, 25, 30)) {
  for (m in c(8, 16, 32)) {
    for (proj in c("73", "82")) {
      for (sample in c("encyclo", "kappa-hf-taq", "phusion", "sd-hs", "snp-detect",
                        "taq-hs", "tersus", "tersus-snp-buff", "truseq", "velox")) {
        .df <- read.table(</pre>
            paste("data",
              paste(paste(q, m, paste("polerr", proj, sep=""), sep="_"), sample,
                     "variant.caller.txt", sep = "."),
                     sep = "/"),
            header=T, sep="\t", stringsAsFactors = F)
        .df$q <- q
        .df$m <- m
        .df$proj <- proj</pre>
        .df$sample <- sample
        df <- rbind(df, .df)</pre>
    }
 }
}
df <- subset(df, count > 0 &
                !grepl("D", mutation) & !grepl("I", mutation) & global.est == 0 &
               coverage > 0)
df$mut.split <- sapply(df$mutation, function(x) strsplit(as.character(x), "[S:>]"))
df$mutation.pos <- as.integer(sapply(df$mut.split, function(x) x[2]))</pre>
df$mutation.from <- sapply(df$mut.split, function(x) x[3])</pre>
df$mutation.to <- sapply(df$mut.split, function(x) x[4])</pre>
df$mut.split <- NULL</pre>
```

Minor-based error model fitting for observed PCR error rate:

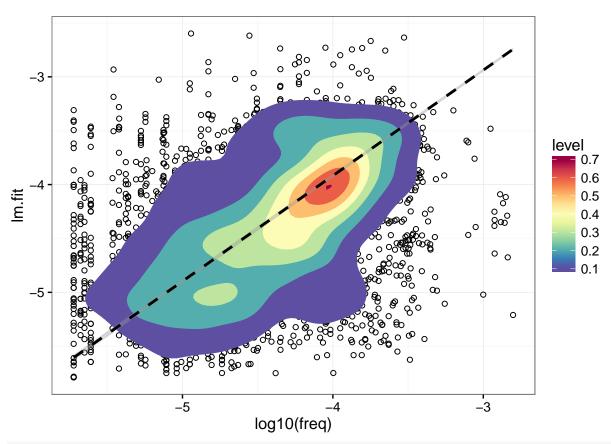

Note that 0-order model is used here. Same polymerase was used during linear PCR to attach UMI and at subsequent PCR cycles. Thus per cycle error rate computed from errors within MIGs should nicely reflect observed error rate.

```
rf <- colorRampPalette(rev(brewer.pal(11, 'Spectral')))</pre>
r < - rf(32)
ggplot(df, aes(x=freq, y=error.rate)) +
  stat_binhex() +

Computing Q-scores for errors using a composite Log Normal + Beta Binomial model and comparing them with real Q-scores.

Beta Binomial model parameters are estimated using mean and sd of fitting performed in previous section

Beta Binomial P-value is computed for variant **counts** in they are ≤ 5 , Log Normal model for **frequencies** is computed otherwise

Q score distributions are compared using QQ plot

The threshold of 5 chose empirically, decreasing and increasing them will under- and over-estimate Q-scores respectively
